POSITION PAPER

THE OPIOID CRISIS IN NORTH AMERICA

October 2017
Throughout the crisis, media accounts have tended to highlight “innocent victims”—people who became addicted following medical exposure to opioids. However, data from the United States from recent years shows that 70-80% of people who misuse medical opioids get them from sources other than their doctor: usually from family and friends or simply by taking them from other people’s medicine cabinets. And while chronic pain is highest among older people, addiction risk is highest among the young. New addictions are uncommon among pain patients who do not have current or past addictions (including alcoholism) or mental illness. It has further been reported that the availability of prescription opioids has increased among those already using drugs.

INADEQUATE TREATMENT AND OTHER SERVICES

North Americans who have become addicted to prescription opioids find health systems completely unprepared to deal with their needs. In both the United States and Canada, treatment is still dominated by abstinence-focused programs. Relapse following detoxification is extremely common and, in this period, the risk of overdoses is heightened due to loss of tolerance. In contrast, opioid substitution therapy has been proven to reduce mortality, typically using methadone or buprenorphine.

Prejudice against opioid substitution therapy with methadone and buprenorphine—and the over-regulation of these drugs—has negatively affected the response to the crisis. In the United States, as of 2015, only 8-10% of treatment programs offered opioid substitution therapy; often provided for periods too limited to be effective. Insurance coverage of addiction treatment has improved to some extent and “parity” with treatment for physical conditions is required under the Affordable Care Act. Treatment providers are not required, however, to meet any federal standards, and the care on offer is rarely based on evidence.

Outright fraudulent, abusive and neglectful treatment is common.

Over-regulation of opioid substitution therapy also means that methadone treatment is provided only in specialized,

**OPIOID SUBSTITUTION THERAPY, MAINTENANCE AND MEDICATION ASSISTED TREATMENT**

Opioid substitution therapy (OST), also called opioid replacement therapy (ORT), opioid agonist therapy (OAT) or maintenance, involves replacing street opioid use with medical use under some degree of supervision, typically with a longer-acting opioid. Commonly used drugs for opioid substitution therapy are methadone or buprenorphine (Suboxone, Subutex).

Opioid substitution therapy, continued as long as needed, including indefinitely, is the only treatment repeatedly shown to cut the death rate from opioid addiction by 50% or more and is the most effective known treatment for opioid addiction according to the World Health Organization (WHO). It is endorsed by several UN agencies, the US National Institute on Drug Abuse, Health Canada, the UK’s National Institute of Health and Care Excellence, the US Institute of Medicine, and many others. It has been repeatedly shown to reduce the spread of HIV and other blood-borne diseases, reduce drug use and injecting, as well as cutting crime.

When on opioid substitution therapy, a person does not get “high” and does not suffer from withdrawal symptoms. Craving is reduced. Addiction is replaced by physical dependence. Once stabilized, most patients can drive, work and care for their families; benefiting from no longer being criminalized. Other patients, however, can still benefit from opioid substitution therapy because it reduces overdose risk by maintaining tolerance to opioids (i.e. a patient who relapses and uses heroin can withstand the dose they were used to) and reducing the rate of use.

There is significant literature from Europe demonstrating that providing supervised access to pharmaceutical heroin itself (heroin-assisted treatment or HAT) is effective for the small number of people for whom methadone treatment does not work. Drugs like hydromorphone (Dilaudid) are also showing promise.

In the United States, a monthly injectable form of long-acting naltrexone (Vivitrol) was approved in 2010 as a third medication option for opioid addiction treatment. In the United States, opioid substitution therapy and extended release naltrexone are grouped together in the category “medication assisted treatment” (MAT), to distinguish these treatments from abstinence-only methods. Less than half a dozen trials of long-acting naltrexone have been published and they show promising results in terms of reducing relapse. There is little long-term data, however, and extended-release naltrexone has not been shown to reduce mortality or disease. It may even increase overdose death risk upon cessation. Vivitrol is not approved in Canada, although it is available under the country’s special access program in reaction to the opioid crisis.
Prejudice against opioid substitution therapy with methadone and buprenorphine—and the over-regulation of these drugs—has negatively affected the response to the crisis. In the United States, as of 2015, only 8-10% of treatment programs offered opioid substitution therapy.41

Considered Outcomes

• Retention
• Illicit Opioid Use

Combined psychosocial and agonist maintenance interventions for treatment of opioid dependence

Authors' conclusions:

For the considered outcomes, it seems that adding any psychosocial support to standard maintenance treatments do not add additional benefits. Data do not show differences also for contingency approaches, contrary to all expectations. Duration of the studies was too short to analyse relevant outcomes such as mortality. It should be noted that the control intervention used in the studies included in the review on maintenance treatments, is a program that routinely offers counselling sessions in addition to methadone; thus the review, actually, did not evaluate the question of whether any ancillary psychosocial intervention is needed when methadone maintenance is provided, but the narrower question of whether a specific more structured intervention provides any additional benefit to a standard psychosocial support. These interventions probably can be measured and evaluated by employing diverse criteria for evaluating treatment outcomes, aimed to rigorously assess changes in emotional, interpersonal, vocational and physical health areas of life functioning.
Discontinuing

The majority of patients who discontinued BMT did so involuntarily, often due to failure to follow strict program requirements, and 1 month following discontinuation, rates of relapse to illicit opioid use exceeded 50% in every study reviewed.

173 persons in office-based maintenance Suboxone treatment, followed for six months. No time limit on their use of Suboxone.
Suboxone and 12-steps

At 18 months, the 76% of patients on continuous Suboxone

**less likely** to report
- using any substance
- using heroin
- damaging a close relationship
- doing regretful or impulsive things
- hurting family
- experiencing negative personality changes
- failing to do things expected of them
- taking foolish risks
- being unhappy
- having money problems

**more likely** to report
- AA “home group”
- “sponsor”
- attending 3+ 12-step meetings per week
- to have been employed at baseline
- to be employed at follow-up

Medication First Model

Housing First is a homeless assistance approach that prioritizes providing people experiencing homelessness with permanent housing as quickly as possible – and then providing voluntary supportive services as needed. This approach prioritizes client choice in both housing selection and in service participation.
Medication First Model

Medication First attempts to get persons with opioid use disorder maintenance medical treatment as quickly as possible and then provides voluntary supportive services as needed. This approach prioritizes client choice in both service selection and service participation.
WHO guidelines

• p. 19-20 "treatment services should not deny effective medication if they are unable to provide psychosocial assistance, or if patients refuse"

• p. 38 "While patients should be offered psychosocial support, they should not be denied agonist maintenance treatment should they refuse such support."

• Persons with OUD should receive medical stabilization prior to undergoing lengthy assessment processes or psychosocial interventions.

• Individualized psychosocial treatment should be offered to patients, but not required as a condition of medical treatment.
• Medical treatment should never be withdrawn unless it is clearly worsening the patient's condition.

• The medical management of OUD should be ongoing, not subject to arbitrary time limits or tapering requirements.

Abbreviations: MAT, medications for addiction treatment; RIDOC, Rhode Island Department of Corrections.

a Some medications for treatment of addiction were in use at RIDOC in specialized circumstances. Treatment with an opioid agonist is standard of care for pregnant women with opioid use disorder. Pregnant women with opioid use disorder incarcerated at RIDOC are typically treated with methadone and less frequently with buprenorphine. A pilot study providing naltrexone by injection had been ongoing since December 2015 prior to the start of the MAT program at RIDOC.

4 Principles of the Medication First Model:

1. People with OUD receive pharmacotherapy treatment as quickly as possible, prior to lengthy assessments or treatment planning sessions;
2. Maintenance pharmacotherapy is delivered without arbitrary tapering or time limits;
3. Individualized psychosocial services are continually offered but not required as a condition of pharmacotherapy;
4. Pharmacotherapy is discontinued only if it is worsening the person’s condition.
